

Autonomic Nervous System Activity in Emotion: A Review

Kreibig (2010), Biological Psychology 84 · tags: gsr, gsr_scr, sympathetic, stress, arousal, physio

VERBATIM EXCERPT (source: gruberpeplab.com course reading copy)

"Anger: Physiological responding in anger-eliciting contexts of harassment or personalized recall describe a modal response pattern of reciprocal sympathetic activation and increased respiratory activity, particularly faster breathing."

"Anxiety ... has been almost unanimously characterized by sympathetic activation and vagal deactivation, a pattern of reciprocal inhibition, together with faster and shallower breathing."

"For electrodermal measures, skin conductance level is the response variable most often reported, followed by skin conductance response rate and skin conductance response amplitude."

Relevance to MedOracle: this is the source for treating elevated GSR / skin conductance as an index of sympathetic (stress, fear, anxiety, anger) activation, and for mapping CREMA-D's FEA label to the 'stress' class.
